Automation Cracker(Ecosystem).net - www.automationcracker.net Port:As described in the above-referenced patent applications, certain systems and methods may be used to extend the service life of a photovoltaic-powered system. To illustrate, if a photovoltaic (PV) system has a maximum output, then the PV system may "spread" the output. This is done through the use of "shunt-connected" voltage-drop means and/or by means of a current-limiting, filter-based load that is connected in parallel with the PV system. The purpose of the shunt-connected means and/or filter-based load is to limit the load current to that which is necessary for the PV system to perform to its maximum output. The shunt connected voltage drop means are not connected across the PV system but rather are connected in parallel with the PV system. In this way, the maximum output of the PV system may be spread across a longer period of time. As described in the above-referenced patent applications, one or more algorithms may be implemented in order to spread the PV system output as efficiently and effectively as possible. There are certain improvements and/or alternatives to the above-described methods. One such improvement and/or alternative is to use a three-terminal device (e.g., a MOSFET, etc.). The three-terminal device is used to spread the PV system output. When the voltage across the three-terminal device is less than or equal to the breakdown voltage, the three-terminal device serves as a switch to allow current to flow from the negative terminal000000011011... PNNNNN... 12.V. In this way, the system may be operated closer to the maximum output voltage of the PV system. Another improvement and/or alternative to the above-described methods is to use a three-terminal
