If your main goal is to edit and retouch images, Lightroom 5 offers the best performing editing application to date. There are a few limitations in its functionality, though. These include the need to fill in image information, the inability to select full-resolution images for non-Photoshop editors, the loss of functionality when images are sent to Photoshop, a limitation on seeing your images in the browser, and the loss of functionality when you open a browser from Lightroom. This is a big drawback for me, even if you do have Lightroom set as default and can always switch to Photoshop without losing data. For editing, though, Lightroom 5 is one of the best programs available. Lightroom makes it easy to create stunning videos with a wide range of video effects and subtleties. You can shoot and edit movies using a single program. You can also add multiple clips from a single event, which allows you to create a clip for each friend in a wedding party or for the boss from behind, or you can merge clips into a single edit. Footage from a DSLR camera with a single HD camcorder can show your potential clients an amazing video—a video to enhance your business or career. The program seems to do a good job at removing unwanted and fuzzy objects. This is especially true in the content-aware options. The setting is relatively straightforward. The beveling effects can be a bit fussy, but in most cases they do the job. The eraser tool worked best when I was using an already established object as the target — its arc-thickness feature can work in a pinch, as a not-so-sharp mask effect. If you need a fly-by-night sharpening effect, use the clone stamp tool on a separate layer in Photoshop.

Photoshop's high level of complexity, unique characteristics, as well as the amount of data processed using the software in a single image, make Photoshop a heavy load on the graphics hardware. To accomplish heavy-duty optimisations and performance that are demanded by photoshopping on a computer with a single-core processor or slower PC, Photoshop gains performance by making use of various technological advances. The first of these includes the use of a powerful graphics engine called APIPT (Automatic Pipeline Technique). APIPT uses the GPU in modern GPUs to accelerate image data calculation. Aside from APIPT, PMD (Physical Device) is another key acceleration technique.* Photoshop uses the strokes (i.e., defines the outline of a gradient) to display certain shades. However, the process of defining the strokes with raster data first requires binarization . Binarization can be done by dithering (the process of rendering pixels to black and white) or by discretizing the gradient. In general, different light sources have different colours. For example, white light is usually perceived as being white , whereas blue is usually perceived as being ultraviolet . The combination of colours perceived as white light is called white point . In digital colour space, the white point can be represented by a single gamma value and is detailed by gamma correction . Nowadays, the purpose of gamma correction is to calibrate the gamma curve of the monitor/display. The gamma curve is used to perform gamma correction. The gamma curve is set to 2.2 for standard culture and 2.4 for European culture.
